
Transport Layer

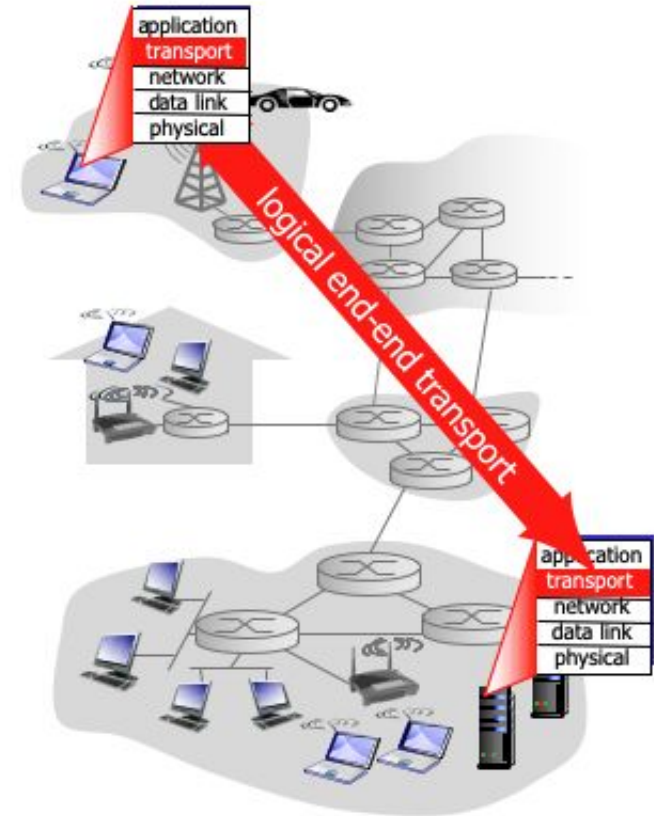

CS5700 Fall 2019

Agenda

- Transport layer services
- UDP
- Reliable data transfer
- TCP
- Congestion control

Transport services and protocols

- Provide logical communication between application processes
- Run in end systems (not the core)
- More than one transport protocol available to applications
 - TCP and UDP

What does network layer do?

- What's the difference between transport layer and network layer?
- What services are provided by network layer?

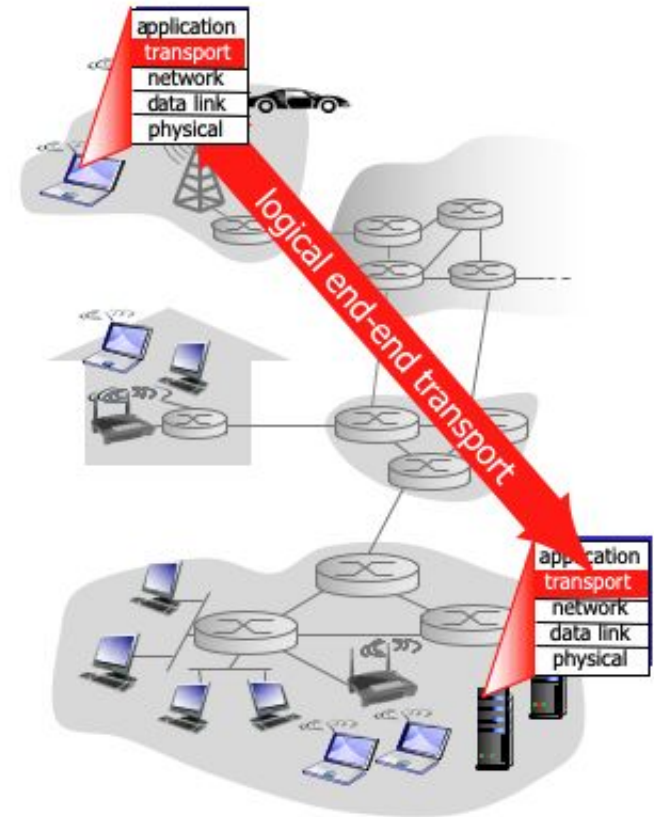

Network layer service model

- Logical communication between hosts
- Every packet is treated individually and separately
- **Best effort**. No guarantee of delivery.

Transport layer protocols

- TCP
 - Reliable in-order delivery
 - Connection oriented
 - Flow control
 - Congestion control
- UDP
- Services not available
 - Delay or bandwidth guarantee

UDP

UDP

- User Datagram Protocol
 - Connection less
 - No guarantee of delivery
- Where do you see UDP used? Do you know why?

UDP header

- Do you know what's each field for?

16 bit source port	16 bit destination port
16 bit UDP length	16 bit UDP checksum
Data	

UDP checksum

- Detect “errors” (e.g. flipped bits) in transmitted segment
- Sender
 - Treat data (include header) as seq of 16-bit integers
 - Add them up (1’s complement), call it checksum
 - Put checksum into UDP header
- Receiver
 - Same algorithm, compute checksum and compare

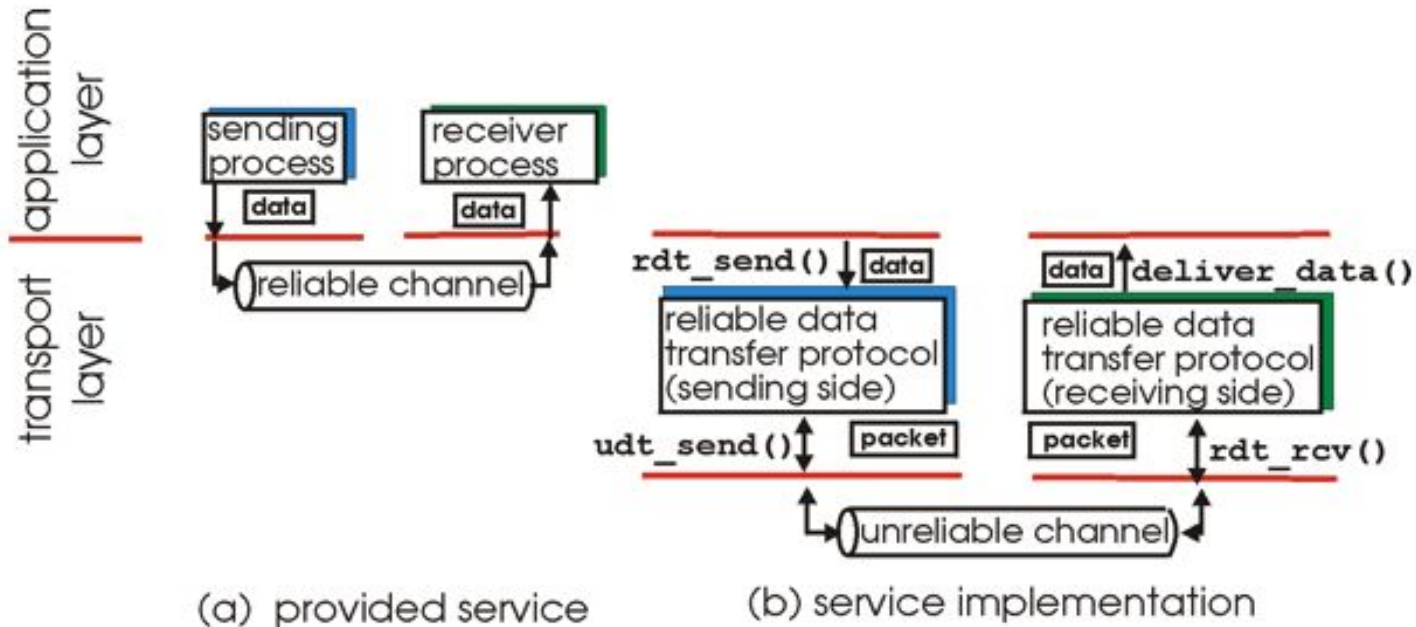

UDP socket

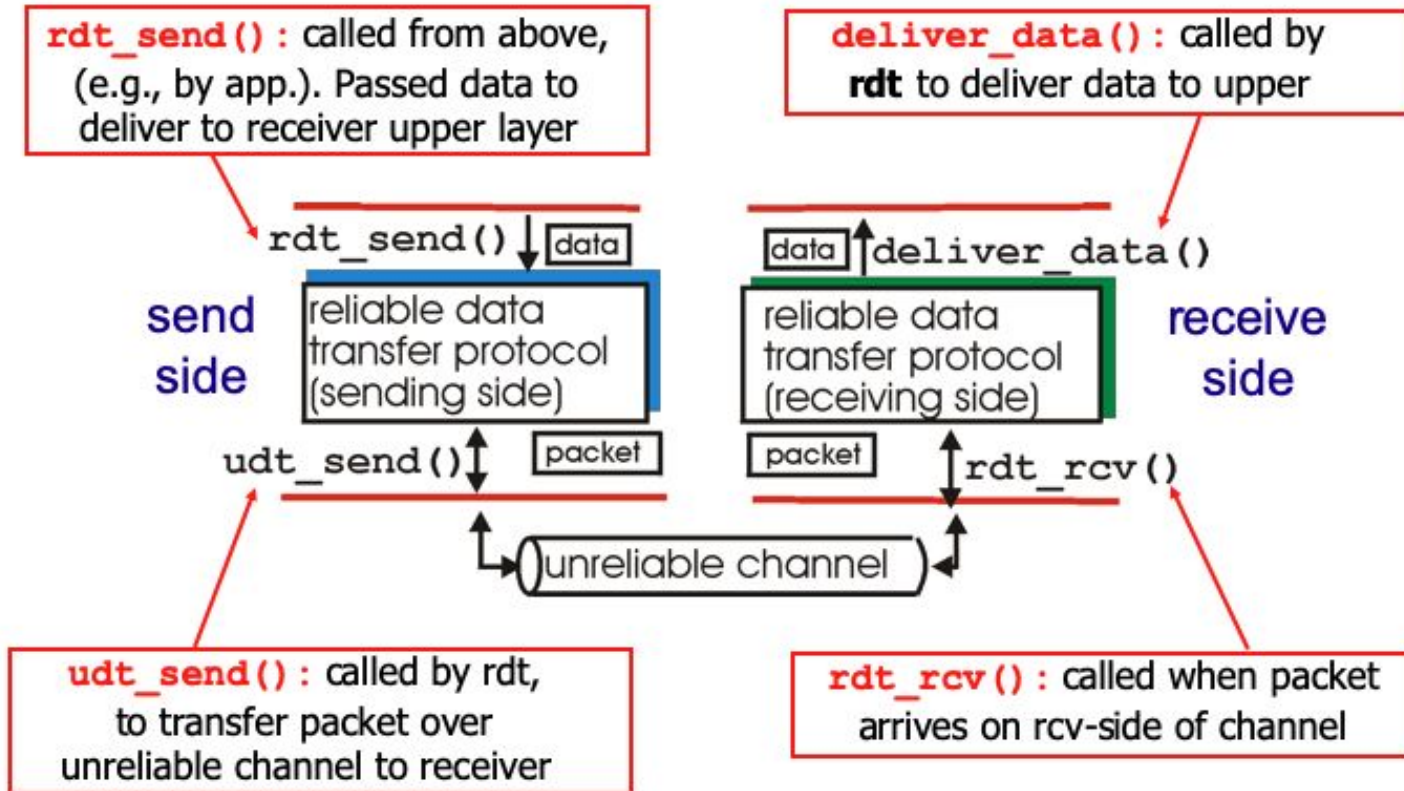

Reliable data transfer

Reliable data transfer

- Important in application, transport, and link layers

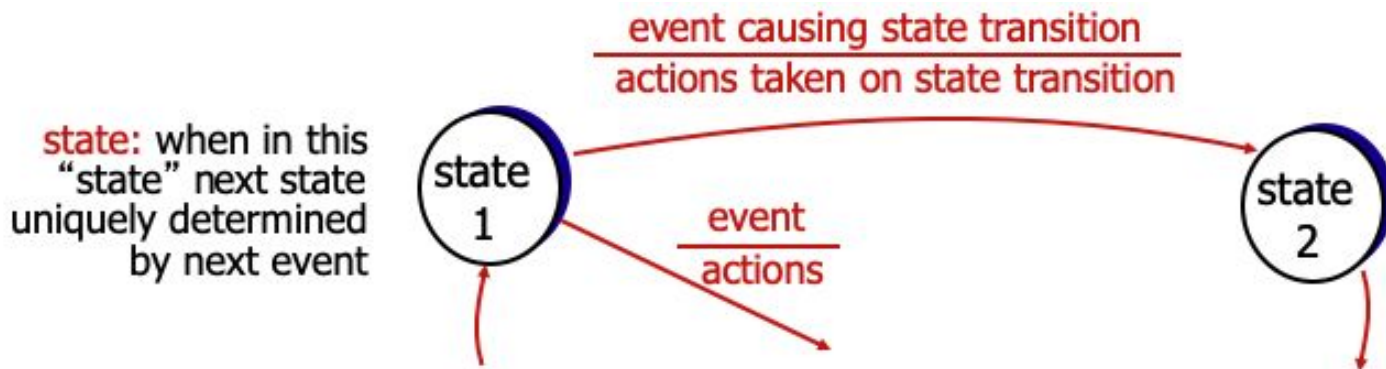

Reliable data transfer

Reliable data transfer

- Incrementally design sender/receiver of rdt
- Consider only unidirectional data transfer
 - But control info will flow on both directions
- Use FSM (finite state machines) to design algorithm

rdt1.0: over a reliable channel

- Underlying channel is perfectly reliable
 - No bit errors
 - No loss of packets

sender

receiver

rdt2.0: channel with bit errors

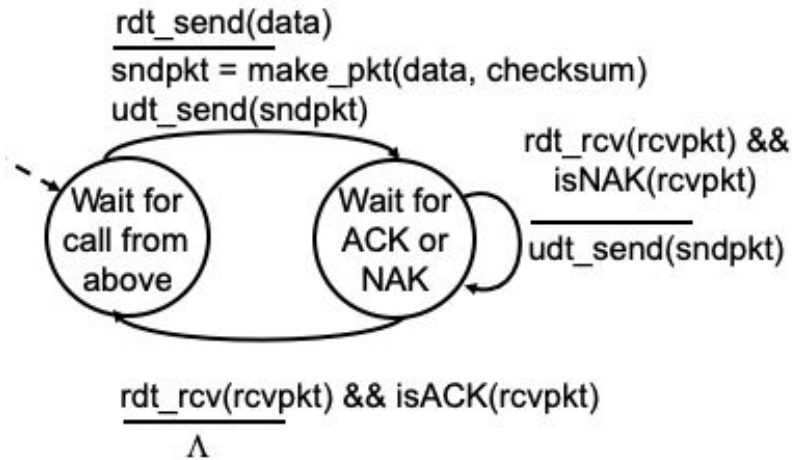

- Underlying channel may flip bits in packet
 - Checksum to detect bit errors
- How to recover from errors?

rdt2.0: channel with bit errors

- ACK (acknowledgement)
 - Receiver explicitly tells sender that pkt received OK
- NAK (negative acknowledgement)
 - Receiver explicitly tells sender that pkt had errors
- Sender needs to retransmit pkt on receipt of NAK
- Summary
 - Error detection
 - Feedback with control message ACK and NAK

rdt2.0: FSM

sender

receiver

rdt2.0: anything looks wrong?

rdt2.0

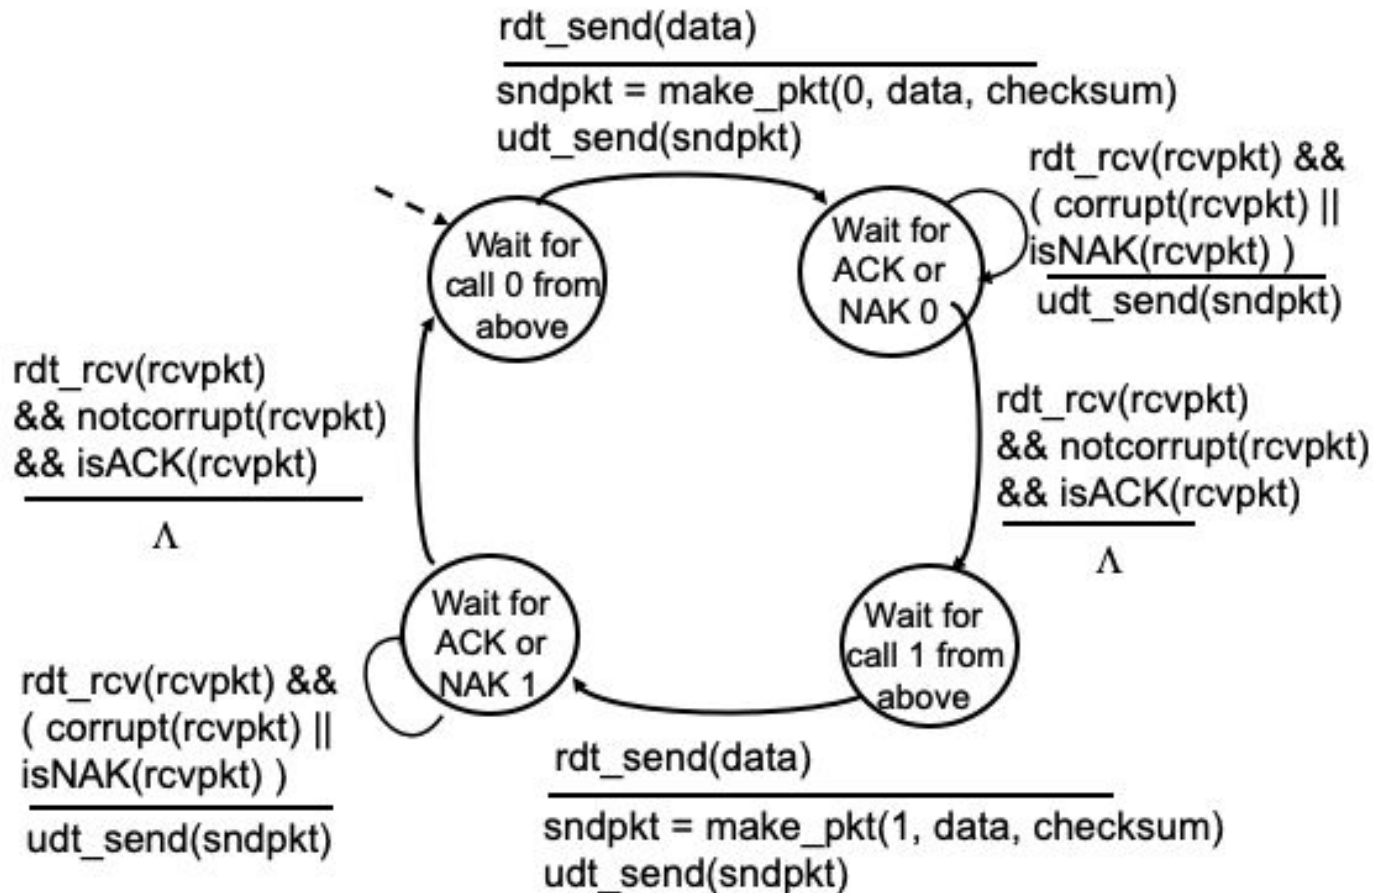

- What happens if ACK or NAK is corrupted?
 - Sender doesn't know what happened at receiver
- Can sender just retransmit?

rdt2.0

- Receiver needs to handle duplicates when sender retransmit
- Need to use sequence number!
- Stop and wait algorithms
 - Sequence number either 0 or 1

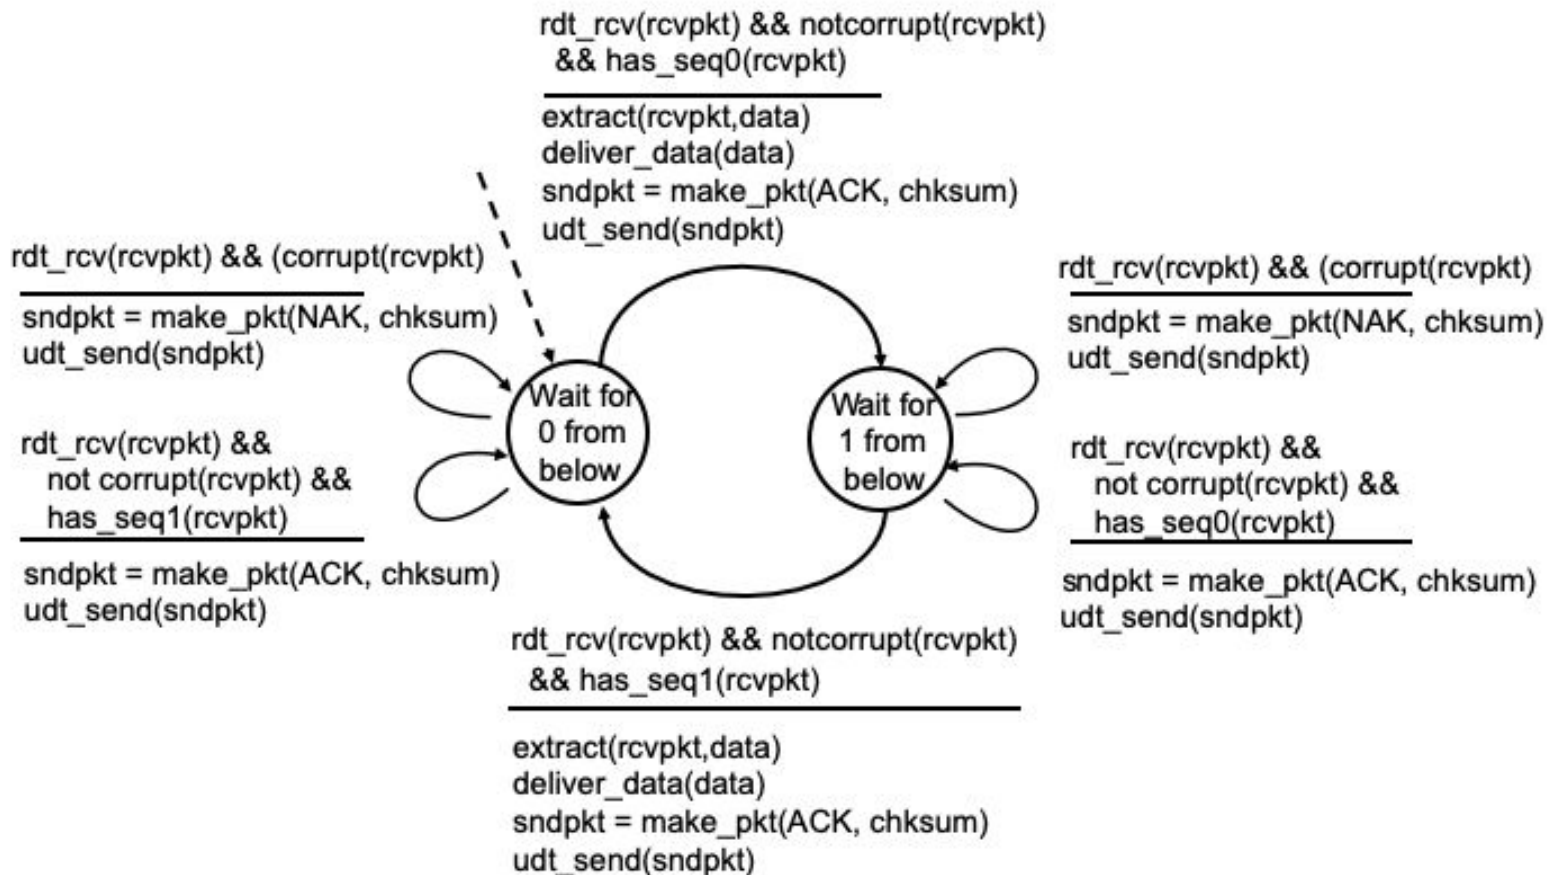

rdt2.1

Sender

rdt2.1

Receiver

rdt2.1: summery

- Sender
 - Add sequence number to packets (either 0 or 1)
 - Retransmit if receives NAK
 - Retransmit if ACK/NAK is corrupted
- Receiver
 - Check if received packet is duplicate (use seq #)
 - Send ACK or NAK for each packet
